

shared habitats in the ecofield By redefining architecture as an abiotic habitat condition, the built environment becomes a suitable living environment for species. Shared Habitats therefore creates an environment where these species can co-exist with humans. A new strategy is developed for this approach, called the ecofield. The ecofield includes architecture as part of the ecological flows and conditions of the landscape. Architecture becomes a key-link within the cohesion of ecosystems on a large scale. The ecofield that stretches from the city center of Haarlem to the sea is marked by eight different landscape typologies. A recreational and contemplative walking route crosses the landscape and eight different 'nestling spaces' are designed along this route, wherein humans and other species can find shelter. These nestling spaces will stabilize, activate and increase the biodiversity by dispersion of species along the whole ecofield. At the same time the design enables humans to experience these habitats in unique ways along their walks. It will generate awareness how every being exists through the existence of another being in the field. The fusion of the conditions designed for the species and the recreational program results in an architecture of niches. Microclimates are created on the scale of the landscape, up to the detailed scale of materialization and texture. This results in a landscape where all habitats — built and unbuilt — are linked, and where every living being can thrive. All inhabiting the continuous ecofield in a shared reality.
